The Multiplicities of a Dual-thin Q-polynomial Association Scheme

Bruce E. Sagan John S. Caughman, IV

Dept. of Mathematics Michigan State University E. Lansing, MI 44824-1027

Abstract. Let $Y = (X, \{R_i\}_{0 \le i \le D})$ denote a symmetric association scheme, and assume that Y is Q-polynomial with respect to an ordering $E_0, ..., E_D$ of the primitive idempotents. In [1, p.205], Bannai and Ito conjectured that the associated sequence of multiplicities m_i ($0 \le i \le D$) of Y is unimodal. We prove that if Y is dual-thin in the sense of Terwilliger, the sequence of multiplicities satisfies $m_i \le m_{i+1}$ and $m_i \le m_{D-i}$ for i < D/2.

1 Introduction

For a general introduction to association schemes, we refer to [1], [2], [5], or [7]. Our notation follows that found in [3].

Throughout this article, $Y = (X, \{R_i\}_{0 \le i \le D})$ will denote a symmetric, D-class association scheme. Our point of departure is the following well-known result of Taylor and Levingston.

1.1 Theorem. [6] If Y is P-polynomial with respect to an ordering $R_0, ..., R_D$ of the associate classes, then the corresponding sequence of valencies

$$k_0, k_1, \ldots, k_D$$

is unimodal. Furthermore,

$$k_i \le k_{i+1}$$
 and $k_i \le k_{D-i}$ for $i < D/2$.

Indeed, the sequence is log-concave, as is easily derived from the inequalities $b_{i-1} \geq b_i$ and $c_i \leq c_{i+1}$ (0 < i < D), which are satisfied by the intersection numbers of any P-polynomial scheme (cf. [5, p. 199]).

In their book on association schemes, Bannai and Ito made the dual conjecture.

1.2 Conjecture. [1, p. 205] If Y is Q-polynomial with respect to an ordering $E_0, ..., E_D$ of the primitive idempotents, then the corresponding sequence of multiplicites

$$m_0, m_1, \ldots, m_D$$

is unimodal.

Bannai and Ito further remark that although unimodality of the multiplicities follows easily whenever the dual intersection numbers satisfy the inequalities $b_{i-1}^* \geq b_i^*$ and $c_i^* \leq c_{i+1}^*$ (0 < i < D), unfortunately these inequalities do not always hold. For example, in the Johnson scheme $J(k^2, k)$ we find that $c_{k-1}^* > c_k^*$ whenever k > 3. However, our main result shows that under a suitable restriction on Y, the multiplicities satisfy the inequalities

$$m_i \le m_{i+1}$$
 and $m_i \le m_{D-i}$ for $i < D/2$.

To state our result more precisely, we first review a few definitions. Let $\operatorname{Mat}_X(\mathbb{C})$ denote the \mathbb{C} -algebra of matrices with entries in \mathbb{C} , where the rows and columns are indexed by X, and let $A_0,...,A_D$ denote the associate matrices for Y. Now fix any $x \in X$, and for each integer i $(0 \le i \le D)$, let $E_i^* = E_i^*(x)$ denote the diagonal matrix in $\operatorname{Mat}_X(\mathbb{C})$ with yy entry

$$(E_i^*)_{yy} = \begin{cases} 1 & \text{if } xy \in R_i, \\ 0 & \text{if } xy \notin R_i. \end{cases} \quad (y \in X).$$
 (1)

The Terwilliger algebra for Y with respect to x is the subalgebra T = T(x) of $\operatorname{Mat}_X(\mathbb{C})$ generated by $A_0,...,A_D$ and $E_0^*,...,E_D^*$. The Terwilliger algebra was first introduced in [7] as an aid to the study of association schemes. For any $x \in X$, T = T(x) is a finite dimensional, semisimple \mathbb{C} -algebra, and is noncommutative in general. We refer to [3] or [7] for more details. T acts faithfully on the vector space $V := \mathbb{C}^X$ by matrix multiplication. V is endowed with the inner product $\langle \ , \ \rangle$ defined by $\langle u, v \rangle := u^t \overline{v}$ for all $u, v \in V$. Since T is semisimple, V decomposes into a direct sum of irreducible T-modules.

Let W denote an irreducible T-module. Observe that $W = \sum E_i^* W$ (orthogonal direct sum), where the sum is taken over all the indices i ($0 \le i \le D$) such that $E_i^* W \ne 0$. We set

$$d := |\{i : E_i^* W \neq 0\}| - 1,$$

and note that the dimension of W is at least d+1. We refer to d as the diameter of W. The module W is said to be thin whenever $\dim(E_i^*W) \leq 1$ $(0 \leq i \leq D)$. Note that W is thin if and only if the diameter of W equals $\dim(W) - 1$. We say Y is thin if every irreducible T(x)-module is thin for every $x \in X$.

Similarly, note that $W = \sum E_i W$ (orthogonal direct sum), where the sum is over all i ($0 \le i \le D$) such that $E_i W \ne 0$. We define the *dual diameter* of W to be

$$d^* := |\{i : E_i W \neq 0\}| - 1,$$

and note that dim $W \ge d^* + 1$. A dual thin module W satisfies dim $(E_i W) \le 1$ $(0 \le i \le D)$. So W is dual thin if and only if dim $(W) = d^* + 1$. Finally, Y is dual thin if every irreducible T(x)-module is dual thin for every vertex $x \in X$.

Many of the known examples of Q-polynomial schemes are dual thin. (See [8] for a list.) Our main theorem is as follows.

1.3 Theorem. Let Y denote a symmetric association scheme which is Q-polynomial with respect to an ordering $E_0, ..., E_D$ of the primitive idempotents. If Y is dual-thin, then the multiplicities satisfy

$$m_i \leq m_{i+1}$$
 and $m_i \leq m_{D-i}$ for $i < D/2$.

The proof of Theorem 1.3 is contained in the next section.

We remark that if Y is bipartite P- and Q-polynomial, then it must be dual-thin and $m_i = m_{D-i}$ for i < D/2. So Theorem 1.3 implies the following corollary. (cf. [4, Theorem 9.6]). **1.4 Corollary.** Let Y denote a symmetric association scheme which is bipartite P- and Q-polynomial with respect to an ordering $E_0, ..., E_D$ of the primitive idempotents. Then the corresponding sequence of multiplicites

$$m_0, m_1, \ldots, m_D$$

is unimodal.

2 Proof of the Theorem

Let $Y = (X, \{R_i\}_{0 \le i \le D})$ denote a symmetric association scheme which is Q-polynomial with respect to the ordering $E_0, ..., E_D$ of the primitive idempotents. Fix any $x \in X$ and let T = T(x) denote the Terwilliger algebra for

Y with respect to x. Let W denote any irreducible T-module. We define the $dual\ endpoint$ of W to be the integer t given by

$$t := \min\{i : 0 \le i \le D, E_i W \ne 0\}. \tag{2}$$

We observe that $0 \le t \le D - d^*$, where d^* denotes the dual diameter of W.

- **2.1 Lemma.** [7, p.385] Let Y be a symmetric association scheme which is Q-polynomial with respect to the ordering $E_0, ..., E_D$ of the primitive idempotents. Fix any $x \in X$, and write $E_i^* = E_i^*(x)$ $(0 \le i \le D)$, T = T(x). Let W denote an irreducible T-module with dual endpoint t. Then
 - (i) $E_i W \neq 0$ iff $t < i < t + d^*$ (0 < i < D).
 - (ii) Suppose W is dual-thin. Then W is thin, and $d = d^*$.
- **2.2 Lemma.** [3, Lemma 4.1] Under the assumptions of the previous lemma, the dual endpoint t and diameter d of any irreducible T-module satisfy

$$2t+d > D$$
.

Proof of Theorem 1.3. Fix any $x \in X$, and let T = T(x) denote the Terwilliger algebra for Y with respect to x. Since T is semisimple, there exists a positive integer s and irreducible T-modules $W_1, W_2, ..., W_s$ such that

$$V = W_1 + W_2 + \dots + W_s$$
 (orthogonal direct sum). (3)

For each integer $j, 1 \leq j \leq s$, let t_j (respectively, d_j^*) denote the dual endpoint (respectively, dual diameter) of W_j . Now fix any nonnegative integer i < D/2. Then for any $j, 1 \leq j \leq s$,

$$\begin{array}{lll} E_iW_j \neq 0 & \Rightarrow & t_j \leq i & \text{(by Lemma 2.1(i))} \\ & \Rightarrow & t_j < i+1 \leq D-i \leq D-t_j & \text{(since } i < D/2) \\ & \Rightarrow & t_j < i+1 \leq D-i \leq t_j+d_j^* & \text{(by Lemmas 2.1(ii), 2.2)} \\ & \Rightarrow & E_{i+1}W_j \neq 0 \text{ and } E_{D-i}W_j \neq 0 & \text{(by Lemma 2.1(i))}. \end{array}$$

So we can now argue that, since Y is dual thin,

$$\dim(E_i V) = |\{j : 0 \le j \le s, E_i W_j \ne 0\}|$$

$$\le |\{j : j \le j \le s, E_{i+1} W_j \ne 0\}|$$

$$= \dim(E_{i+1} V).$$

In other words, $m_i \leq m_{i+1}$. Similarly,

$$\begin{aligned} \dim(E_i V) &= |\{j : 0 \le j \le s, E_i W_j \ne 0\}| \\ &\le |\{j : 0 \le j \le s, E_{D-i} W_j \ne 0\}| \\ &= \dim(E_{D-i} V) \end{aligned}$$

This yields $m_i \leq m_{D-i}$.
